MRI SHOULDER RIGHT W CONTRAST

Collected on May 8, 2018 10:27 AM

Novant Health

Results

Impression

IMPRESSION:

1. No visualized rotator cuff or labral tear.
2. Suspected mild strain of the infraspinatus muscle.

Narrative

MRI SHOULDER RIGHT W IV CONTRAST 5/8/2018 9:23 AM

INDICATION: evaluate for labral tear and instability

COMPARISON: None.

TECHNIQUE: Multiplanar imaging of the shoulder was performed with intra-articular contrast.

FINDINGS:

ROTATOR CUFF: No full-thickness rotator cuff tear is identified. No partial-thickness tear is visualized. There is some minimal edema signal which infiltrates the posterior margin of the infraspinatus muscle, suspicious for a strain. No drainable fluid collection is present. No rotator cuff muscle atrophy is present.

GLENOHUMERAL JOINT: There are no definitive lesions of the bony glenoid or cartilaginous labrum.

LONG HEAD BICEPS TENDON: The tendon is intact and located in its normal anatomic position.

ACROMIOCLAVICULAR JOINT: The acromioclavicular joint is well-preserved. Note is made of a type 2 acromion.
